

## USE OF NONINVASIVE RHD GENOTYPING FOR THE Rh NEGATIVE NON-SENSITIZED MOM\*

\* RHD genotyping can also be useful for the Rh sensitized mom. When the fetus is found to be Rh positive, then careful surveillance for the development of hemolytic disease is warranted, and if the fetus is Rh negative, then it is not in danger of developing hemolytic disease.

\*\*Due to the nature of this testing, these patients will still require a 28 week RhD immunoglobulin shot. Additional markers are currently being evaluated that will allow for a more definitive diagnosis in this group of patients.
